The Editors
Physical Review Letters

Dear Editors,

Internal note, not for submission. This letter is retained only to record a judgement made deliberately rather than by omission: we do *not* consider the present result appropriate for PRL, and the manuscript is directed to Physical Review D.

The strongest component is a structural no-go: the quasinormal pencil of the doubly rotating five-dimensional Myers–Perry black hole is a direct sum over azimuthal sectors, so the equal-spin $U(2)$ multiplet degeneracies cannot be defective, and the enhanced symmetry closes the very channel it appears to open. The argument is short and exact, and it rules out a natural expectation.

Against that: the accompanying result is a *bounded negative* classification over a declared parameter domain, not a discovery; the no-go, while exact, follows in two lines from a standard property of direct sums once the decomposition is set up correctly, so its novelty lies in the application rather than the mathematics; and the one regime where an exceptional point could still hide in this system — the quasisonant limit — is precisely the regime our methods cannot reach.

A PRL submission would require either a verified exceptional structure, or a demonstration that the termination law we derive is realized somewhere, neither of which we have. Should the hyperboloidal follow-up we identify as the next step produce either, this assessment should be revisited.

Sincerely,
